#### ABSTRACT

Breeding pair surveys for Harlequin Ducks were done on 409 km of 20 streams during May and June, 1993; a total of 42 Harlequins (27 males, 15 females) were seen on 6 streams. Brood surveys were done on 377 km of 21 streams during July and August, 1993; a total of 78 Harlequins (19 females, 59 young in 21 broods) were seen on 9 streams. Harlequins were reported on an additional 4 streams. Reproductive success, on streams surveyed both for pairs and broods, averaged 0.40 broods per female. Success in the North Fork Flathead drainage was substantially lower (0.32 broods per female) than in the lower Clark Fork drainage (0.60 broods per female). Brood size at or near fledging (Class III) averaged 2.86; August brood sizes were consistent among all drainages. No new breeding streams were confirmed in 1993. No birds were seen during pair (May) or brood (August) surveys of Sullivan Creek, which had Harlequins in 1992.

We continued banding Harlequin Ducks in the Flathead and Clark Fork drainages. Sixtyeight Harlequins (13 adult males, 14 adult females, and 41 juveniles) were marked on 7 streams. This brings the total number of Harlequin Ducks banded in Montana since 1991 to 159 (22 adult males, 34 adult females, and 103 juveniles). We observed 20 previously marked birds on streams. The banding program, while small in scale for waterfowl, is providing a significant tool for local monitoring and identifying coastal areas where Montana breeding birds molt and winter.

Six movements detected in 1993 were interesting. A male marked on McDonald Creek, Glacier National Park, on 6 May 1993, was captured on Hornby Island, along the east coast of Vancouver Island, British Columbia on 5 August 1993. This was the first record of a bird marked in Montana being relocated on the coast. On 14-15 March 1994 three Harlequins were observed

iii

on Hornby Island, all marked as juveniles in 1992-3 on McDonald Creek. Local movements of birds, heretofore undocumented, include two marked females found on different streams in 1993 than where they were originally marked in 1992. Stream mouths were separated by 6 and 17 km respectively, across a reservoir and lake.

# ACKNOWLEDGEMENTS

We thank Bob Summerfield for his help throughout the study. We were assisted with field work by Stan Beckstrom and Chad Castren. Additional help, location of possible trapping sites, and other logistical support was provided by J. Ashley, J. Davies, R. Galloway, S. Gniadek, C.E. Hidy, T. Hidy, W. Johnson, B. Kennedy, E. Pfalzer, H. Rivera, D. Roemer, N. Warren, and other Forest Service and Park Service personnel. M. Beer, C. Jones and C. Craig assisted with element occurrence and map preparation. Financial support for the project came from the Kootenai National Forest (U.S. Forest Service, Northern Region) and the Montana Natural Heritage Program (Montana State Library and The Nature Conservancy).

# INTRODUCTION

The Harlequin Duck (*Histrionicus histrionicus*) is a small sea duck, which travels inland to breed on fresh water streams. The male is strikingly colored with black and white spots and crescents, and chestnut sides on a deep cobalt blue background. The female is dull brown with three white spots on the face. Harlequins breed in western North America from Alaska and the Yukon south through western Montana to California (Cassirer et al. 1993); in eastern North America they breed form Baffin Island south to eastern Quebec and Labrador (Goudie 1993). In the Palaearctic they breed in Iceland, Greenland and Siberia (A.O.U. 1983). Approximately 110 pairs of Harlequins currently breed in Montana (Genter 1993), with most located in the following areas: 1) tributaries of the lower Clark Fork River; 2) tributaries of the North, Middle, and South Forks of the Flathead River; 3) streams coming off the east front of the Rocky Mountains; and 4) the Boulder River (Miller 1988, 1989, Kerr 1989, Carlson 1990, Fairman and Miller 1990, Diamond and Finnegan 1992, 1993).

During the breeding season Harlequins are found along fast mountain streams (Bengston 1966). In many areas Harlequins use streams with dense timber or shrubs on the banks (Cassirer and Groves 1990), but they are also found in relatively open streams along the east slopes of the Rocky Mountains, Montana (Markum and Genter 1990, Diamond and Finnegan 1992) and the Arctic tundra (Bengston 1972). In Idaho, 90% of observations occurred near old growth or mature timber stands (Cassirer and Groves 1990). Mid-stream rocks, logs, islands, or stream-side gravel bars serve as safe loafing sites and appear to be important habitat components.

Most of the ducks arrive on their inland breeding areas in mid-April to early-May; unmated males typically arrive before pairs (Kuchel 1977). The males return to the coast shortly after the females begin incubation; most are gone by early July (Kuchel 1977). The females and

young remain on the streams until August or early September. This chronology is influenced by elevation and the timing of spring runoff and may vary up to several weeks between years.

The U.S. Forest Service, Region 1, lists the Harlequin Duck as Sensitive (Reel at al. 1989). The species is listed as a Species of Special Concern by the Montana (Genter 1992) and Idaho (Moseley and Groves 1990) Natural Heritage Programs. The eastern North American population is listed as endangered in Canada (Goudie 1993); both eastern and western populations are listed under Category 2 as a candidate for listing under the Endangered Species Act by the U.S. Fish and Wildlife Service (U.S. Department of Interior 1991).

The Montana Natural Heritage Program began surveying Harlequin Ducks in 1988. The survey data gave rise to questions involving site fidelity, productivity and mortality. Individual marking of birds began to a limited extent in 1991 and in 1992 a total of 85 Harlequins were marked on 5 streams. Long term goals include: 1) developing a baseline status report of current and historic Harlequin populations in Montana; 2) gathering information on site fidelity, reproduction and mortality to allow estimations of what constitutes viable Harlequin populations; 3) developing surveying protocols for actual and potential Harlequin streams; 4) developing management guidelines for maintaining and restoring Harlequin populations and habitat; and 5) identify coastal areas where Harlequins from the Northern Rockies occur. Goals for 1993 included: 1) surveying additional streams for presence and status of Harlequins; 2) gathering productivity data on some primary Harlequin streams; and 3) marking as many individuals as possible on selected streams for long-term monitoring.

## METHODS AND MATERIALS

Harlequin Ducks were surveyed on parts of the Kootenai, Custer, Flathead, Gallatin, Kaniksu, and Lolo National Forests during May-August 1993. We also marked birds in Glacier National Park; surveys there were conducted primarily by Park Service personnel (John Ashley). Most surveys were conducted by walking the stream channel (when possible) or stream bank. In most cases the surveyor walked upstream, giving more time to observe the bird before it moved out of sight. Some large streams were surveyed by kayak. Dates, locations, km surveyed, and general characteristics of the stream reaches surveyed were recorded; any Harlequins sighted were noted with location, numbers, ages, and sex of birds present. For streams in the Flathead and Clark Fork drainages, we attempted to capture and mark all birds seen, when a licensed, qualified birdbander was present on the survey (Reichel or Genter). Captured birds were identified to sex and age, weighed, measured (wing cord and tail), marked, and released. Except in Glacier National Park, almost all birds were marked with numbered USFWS aluminum leg bands and colored nasal discs, individually recognizable by shape and color combinations (see Appendix B). Birds in Glacier National Park were banded with a USFWS aluminum band and a unique combination of 3 plastic, colored leg bands.

#### **RESULTS AND DISCUSSION**

#### Surveys

Kootenai National Forest. Pair surveys were conducted along 210 km of 9 streams during May-June 1993 (Table 1). A minimum of 20 Harlequins (11 males, 9 females) were seen on 3 streams (Appendix B & C). These included the Vermillion River (3 pairs), Swamp Creek (1 pair) and Marten Creek (5 pairs plus  $2\sigma$ ).

Brood surveys were conducted along 65 km of 4 streams during late July - August 1993 (Table 1). A minimum of 28 different Harlequin Ducks were observed on 3 streams (Table 1, Appendix B & C). Marten Creek had  $2^{\circ}$  present with 2 broods (4,4). Swamp Creek had  $1^{\circ}$ present with a single chick. Rock Creek had  $1^{\circ}$  present with a brood of 4 and 2 additional chicks were present from another brood (the female was not present). The Vermilion River had  $2^{\circ}$ present with 2 broods (4,4) and an additional single chick was present from another brood (the female was not present).

No Harlequins were observed on Elk Creek during our short survey, but a male was seen by F.S. personnel (Table 2).

<u>Flathead National Forest</u>. Pair surveys were conducted along 88 km of 6 streams during May-June 1993 (Table 1). A minimum of 16 Harlequins (10 males, 6 females) were seen on 2 streams (Table 1, Appendix B & C). These included Big Creek (1 $\sigma$ ) and Trail Creek (5 pairs and  $3\sigma$ ); additionally we had a report of Harlequins from Whale Creek (Table 2).

Brood surveys were conducted along 185 km of 11 streams during July - August 1993 (Table 1). A minimum of 26 different Harlequin Ducks were observed on 3 streams (Table 1, Appendix B & C). These included: 1) Middle Fork of the Flathead River (39, 3 broods of 1, 3,

and 4 young), 2) Spotted Bear River (1, 1 brood of 4 young), and 3) Trail Creek (2, 2 broods of 3 & 5 young). No Harlequins were observed on Sullivan Creek where they were observed in 1992.

Custer, Gallatin, Kaniksu, and Lolo National Forests. Pair surveys were conducted along 111 km of 5 streams during May-June 1993 (Table 1). A minimum of 6 Harlequins (6 males) were seen during surveys on 1 stream, the Boulder River in Gallatin NF (Table 1, Appendix B & C). Additionally we had reports of Harlequins from Rattlesnake Creek (pair in 1990: Joe Ball; pair 1989, 1990, 1991).

Brood surveys were conducted along 127 km of 6 streams during July and August 1993 (Table 1). Two different Harlequin Ducks were observed on 1 stream (Table 1, Appendix B & C). The Boulder River had 1 adult female and 1 juvenile present. No Harlequins were observed during surveys of Trout Creek or the North Fork of the Blackfoot River (Lolo NF) where they have been observed in at least one of the past five years.

<u>Glacier National Park</u>. Brood surveys were conducted along 29 km of the McDonald Creek drainage on 10-11 August 1993 (Table 1). A minimum of 22 different Harlequin Ducks ( $6^{\circ}$ ; 6 broods of 1, 2, 2, 3, 4, 4) were observed on McDonald Creek (Table 1, Appendix B & C). Many other surveys were conducted throughout the season by Glacier National Park personnel (Ashley 1993). These surveys found up to 18 adult females present in May.

<u>Breeding Chronology</u>. Breeding was early again this year, probably due to rapid spring runoff in early May. As a result, many females apparently began incubation by 20 May; some males had

left by the second pair survey of Marten Creek on 26 May. The last male was seen on McDonald Creek on 22 June 1992 about 10 days earlier than reported in 1973-75 (Kuchel 1977, Ashley 1993). All young were nearly fledged by the end of July on the Lower Clark Fork drainages and 13 August on Trail Creek. However, most females and young were still present on 10-11 August at McDonald Creek in Glacier National Park, and some young were still downy.

Table 2 (cont.). Miscellaneous reports of Harlequin Ducks during 1993 and reports for prior years received during 1993.

# Reproduction

Harlequins were present this year on at least 12 streams in the study area and adult females or broods were seen on 11 of those streams. A minimum of 43 adult females were present. Late-July to early-August brood size on all streams averaged 2.81 (n=21). This was lower than in 1992 (3.27). Brood size did not vary between the North Fork Flathead and Lower Clark Fork drainages in 1993. Most broods were seen in Class III or fledged stages of development (Bellrose 1976:27), and we made no adjustment for age of broods in our calculation of mean brood size.

Of 37 potential broods on North Fork of the Flathead and lower Clark Fork drainages, a minimum of 16 were produced for a 43% success rate of broods per adult female. From 1989 to 1993 (Table 4), the success rate averaged 46.5% (range= 24-55%; n=200 pairs on 35 streams). In 1993, the differences in success rates between the North Fork Flathead drainage (32%) and the Lower Clark Fork drainage (60%) were large. Annual differences in success rates from 1989-1992 were primarily associated with the amount and timing of runoff. High runoff, particularly in June-early July, and runoff in years with "double peaks" caused lower reproductive success. This was particularly evident in 1991 (Table 4, Figure 2, 3) the only year where runoff exceeded 20,000 cfs and when production was lowest (24%). The changes in reproductive success were primarily due to changes in numbers of broods per pair, not changes in the size of successful broods. This indicates that differences in mortality were due to events that affected entire clutches or very young broods.

# Capture and Marking

We continued to make good progress during the second year of the juvenile Harlequin Duck site fidelity and survival study. A total of 41 juvenile birds from 7 drainages were captured and marked (Table 5, Appendix D & E). Thirteen adult males and 14 adult females were also marked in 1993 (Table 5, Appendix D & E).

## **Relocation and marking effects**

Table 6 shows when and where adults were marked and relocated, and if other ducks were present at the time. Of 6 adult birds marked in 1991 with nasal markers, 4 have been seen in subsequent years; however, 2 males not seen in 1992 were resighted in 1993. Of 11 adult birds marked with nasal discs in 1992, 6 were resighted in 1993. Of 2 females marked in 1991, both successfully raised broods in 1992, and one again in 1993. Of 5 females marked in 1992, 4 were resighted in 1993 and 2 of those successfully raised broods in 1993.

Of 13 adult birds (all females) marked with colored leg bands in 1992, 6 were resighted in 1993 and 2 of those successfully raised broods in 1993.

Adults marked with nasal discs were relocated in the second year at a slightly (nonsignificant) higher rate than birds marked with colored leg bands (47% versus 46%). Females marked with nasal discs which returned in the second year, successfully raised broods at higher rate than those marked with colored leg bands (57% versus 33%). These preliminary results indicate that the use of nasal discs on adult Harlequin females has little if any negative effect on survival or reproductive success.

# Movements

Several movements of note were detected in 1993 (Table 6 and Table 7). A female marked on Marten Creek in August 1992 with a single juvenile was found in August 1993 on Swamp Creek, again with a single juvenile. The mouth of Swamp Creek is 6 km north east (across Noxon Reservoir) of the mouth of Marten Creek.

A female marked with 7 juveniles on McDonald Creek in August 1992 was seen again on McDonald Creek on 8 May 1993 with an unbanded male. On 11 May 1993 she was found with an unbanded male on Fish Creek (John Ashley, pers. comm.). The mouth of Fish Creek is 17 km southwest (across Lake McDonald) of the mouth of McDonald Creek.

Four Harlequins marked on McDonald Creek, Glacier National Park were recaptured or resighted on Hornby Island, off Vancouver Island in August 1993 and March 1994 (Table 7). However, in only a single case was the exact individual able to be identified. These are the first records of birds marked in Montana being relocated in coastal areas.

#### MANAGEMENT RECOMMENDATIONS AND RESEARCH NEEDS

Adult Harlequins show strong fidelity to breeding sites (Bengston 1972, Kuchel 1977, Dzinbal 1982, Wallen 1987). The extent of fidelity to natal areas by adults breeding for the first time is unknown, but is likely to be strong. Colonization of currently unoccupied streams is likely to be a rare event. Harlequins appear sensitive to human disturbance (Clarkson 1992, Cassirer and Groves 1991). Repeated disturbances may discourage nesting at traditional sites and reduce productivity (Rodrick and Milner 1991). However, proximity to trails and roads does not always correlate with reduced reproductive success. Sixty percent of Harlequin sites were within 50 m of trails on the Rocky Mountain Front (Diamond and Finnegan 1992). In this case, most Harlequin streams are located in roadless or wilderness areas and receive limited human activity prior to or during the nesting period.

Mid-stream loafing sites are important in breeding areas (Cassirer and Groves 1990). Brood rearing areas in Idaho and Montana west of the Continental Divide have a dense shrub or timber/shrub mosaic on the banks (Cassirer and Groves 1989, Gangemi 1991). East of the Divide in Montana stream banks are more open, and most observation sites had banks composed of gravel, grass-forb, or bedrock habitat (Diamond and Finnegan 1992, Markum and Genter 1990). Low benthic macroinvertebrate biomass may limit the number and productivity of Harlequins (Bengston and Ulfstrand 1971, Kuchel 1977). Given these factors, we recommend the following management strategies on Harlequin streams:

 minimize unnecessary human activity along Harlequin streams during May through August;
 a stream buffer of > 50 m should be maintained on both sides of streams for most activities; roads and trails should be > 100 m from streams and not visible from the streams;

- major activities (road building, timber harvest, restoration projects, etc.) that are to be undertaken within 300 m of a stream should be done during the period 15 August - 1 April;
- 4) minor activities within stream buffers (e.g. trail maintenance or reconstruction) should not be preformed during 1 May - 15 July;

5) avoid activities which will change stream runoff patterns or decrease water quality;

6) in any area where major management activities are to take place in potential Harlequin habitat, survey for the preceding two years both for pairs (May) and broods (mid-July to mid-August). If Harlequins are present, develop a monitoring plan for Harlequins during and after the activity is to take place.

Long term research and management needs involve:

- develop a baseline status report of current and historic Harlequin populations in Montana (currently in preparation);
- investigate site fidelity, inter-stream movement, reproduction and mortality to allow estimations and modeling of what constitutes a viable Harlequin population (began in 1992);
- determining the primary limiting factors for Harlequin Duck populations in occupied and historic habitat situations in the Northern Rockies;
- 4) developing standardized surveying protocols for occupied and potential Harlequin streams;
- 5) developing management guidelines for maintaining Harlequin populations and habitat; and
- 6) assess the impacts of past and current habitat modification and develop techniques to restore

Harlequin populations and habitat.

Other observations: BOTH BROODS IN ONE GROUP; LOCATION NOT INDICATED.

Histrionicus histrionicus Spotted Bear River (029)

Scientific Name: HISTRIONICUS HISTRIONICUS Common Name: HARLEQUIN DUCK Global rank: G5 Forest Service status: SENSITIVE State rank: S2B, SZN Federal Status: C2 Element occurrence code: ABNJB15010.029 Element occurrence type: Survey site name: SPOTTED BEAR RIVER EO rank: D EO rank comments: NO RECORDS OF MORE THAN 2 PAIRS PRESENT. SOME FISHING AND BOATING. RELATIVELY EASY ACCESS AFTER THE ROAD OPENS (USUALLY AFTER JULY 1). MAY BE PART OF A LARGER SOUTH FORK FLATHEAD RIVER EO. County: FLATHEAD USGS quadrangle: WHITCOMB PEAK Township: Range: Section: TRS comments: 025N 014W 14 13 Precision: M Survey date: Elevation: 4050 - 4200 First observation: 1992-08-13 Slope/aspect: -/-Last observation: 1993-08-15 Size (acres): Location: FROM HUNGRY HORSE, GO UP EAST SIDE OF RESERVOIR TO SPOTTED BEAR RIVER (CA. 50 MILES), THEN UP SPOTTED BEAR RIVER TO BEAVER CREEK CAMPGROUND. Element occurrence data: PROBABLY 1 OR 2 BROODS PRODUCED EACH YEAR. (SPECIFIC OBSERVATION DATA ON FILE AT MTNHP.) General site description: STREAM REACH OF CA. 2 MILES. Land owner/manager: FLATHEAD NATIONAL FOREST, SPOTTED BEAR RANGER DISTRICT Comments: EXTENT OF OCCUPIED BREEDING HABITAT UNKNOWN. NOTE REPORT OF SINGLE FEMALE AT DEAN FALLS, CA. 10 MILES UPSTREAM OF WHITCOMB CREEK, ON 8/4/93. Information source: GENTER, D. L. 1992. [FIELD NOTES FROM 13 AUGUST RE: BANDING HARLEQUIN DUCKS ON SPOTTED BEAR RIVER.]
